

**Assignment #3: Ocean Carbon Chemistry**  
**Due Thursday, Nov 30**

- 1) Use the expressions of chemical equilibria in the ocean carbonate system to calculate the partial pressure (or mole fraction) of CO<sub>2</sub> in the atmosphere, assuming a global average surface salinity of 34.78‰ and temperature of 16 °C:
  - i) For preindustrial equilibrium with surface ocean conditions:
    - TA = 2311 μeq kg<sup>-1</sup>
    - DIC = 2002 μmol kg<sup>-1</sup>
  - ii) For hypothetical equilibrium between the atmosphere and the deep ocean, assuming the entire ocean was mixed and warmed to 16 °C, and with:
    - TA = 2393 μeq kg<sup>-1</sup>
    - DIC = 2288 μmol kg<sup>-1</sup>

*For help please consult the attached article by Tans (1998) and also feel free to copy-paste from the class website (Carbonate Chemistry Toy Model).*

- 2) An empirical relationship between air-sea fluxes and environmental conditions based on a quadratic dependence on wind speed, temperature, salinity, and the difference in pCO<sub>2</sub> between the air and the ocean surface (Wanninkhof, 1992) is widely used to estimate air-sea gas exchange of CO<sub>2</sub>.

Assume that the atmospheric CO<sub>2</sub> mole fraction is 400 ppmv. Using the quadratic wind-speed relationship described in the attached article, calculate the piston velocity (m s<sup>-1</sup>) for air-sea gas exchange and the flux of CO<sub>2</sub> into the ocean (mol CO<sub>2</sub> m<sup>-2</sup> s<sup>-1</sup>) under the following conditions:

- **Arctic ocean:** T=0 °C, wind speed = 20 m s<sup>-1</sup>, sea-surface pCO<sub>2</sub> = 375 μatm, salinity=35‰;
- **Subtropical gyre:** T=26 °C, wind speed = 5 m s<sup>-1</sup>, sea-surface pCO<sub>2</sub> = 398 μatm, salinity=35.5‰;
- **Equatorial East Pacific:** T=21 °C, wind speed = 2 m s<sup>-1</sup>, sea-surface pCO<sub>2</sub> = 425 μatm, salinity=34‰;

*The Wanninkhof article is attached, and you're welcome to copy-paste empirical values of his coefficients from the class website (3-box ocean toy model).*

- 3) Please read the short attached article on Ocean Acidification by Feeley et al (2009).
  - a) Use the values for the modern ocean in Feeley's Table 1 to estimate the pCO<sub>2</sub> and [Ca<sup>2+</sup>] for the North Pacific and the Arctic Ocean.
  - b) Assuming that [Ca<sup>2+</sup>] remains constant, estimate the saturation states for aragonite Ω<sub>ar</sub> and calcite Ω<sub>ca</sub> if atmospheric CO<sub>2</sub> reaches 600 and 1000 ppm.
